

Hidden Markov models

Week 3

Kasper Munch

A weather model

Hidden Markov model

Transitions and emissions

Transition probabilities:

Emission probabilities:

$$\begin{aligned} \text{H:} \quad & P(\text{☀}) = 0.7, & P(\text{☁}) = 0.3 \\ \text{L:} \quad & P(\text{☀}) = 0.3, & P(\text{☁}) = 0.7 \end{aligned}$$

Hidden Markov chain:

Watching the weather channel

Finding the most likely model parameters

Observations:

Model parameters:

$$\begin{array}{ll} \text{H:} & P(\text{sunny}) = 0.7, \quad P(\text{cloudy}) = 0.3 \\ \text{L:} & P(\text{sunny}) = 0.3, \quad P(\text{cloudy}) = 0.7 \end{array}$$

Guessing air pressure yourself

Finding the most likely hidden states

Observations:

Model parameters:

$$\begin{aligned} \text{H: } & P(\text{sunny}) = 0.7, & P(\text{cloudy}) = 0.3 \\ \text{L: } & P(\text{sunny}) = 0.3, & P(\text{cloudy}) = 0.7 \end{aligned}$$

Most likely sequence
of hidden states:

Hidden Markov model

Why are they useful?

1. We can make the HMM **describe data** by optimising its **parameters**.
2. Using the HMM, we can estimate the **most likely sequence of hidden states**.
3. Using the HMM, we can estimate the **probability of each hidden state at each position** in the sequence

Hidden Markov model

Why are they useful?

2. We can make the HMM **describe data** by optimising its **parameters**.
1. Using the HMM, we can estimate the **most likely sequence of hidden states**.
3. Using the HMM, we can estimate the **probability of each hidden state at each position** in the sequence

Markov chain

→ H → H → H → H → L → L → L → L → L → L → H → H →

The Markov property:

The probability of the state at the next position in the chain only depends on the state at the current position.

I.e. the process has no memory.

Markov chain

$$\begin{aligned} P(\pi) &= P(\pi_L | \pi_{L-1}) P(\pi_{L-1} | \pi_{L-2}) \cdots P(\pi_2 | \pi_1) P(\pi_1) \\ &= P(\pi_1) \prod_{i=2}^L P(\pi_i | \pi_{i-1}) \end{aligned}$$

5 min discussion

- What is a state and what is an observable?
- What is hidden and what is observed?
- What is a Markov chain?

Hidden Markov chain

Hidden Markov chain: π

π_1 π_2 π_3 π_4 π_5 π_6 \dots

x_1 x_2 x_3 x_4 x_5 x_6 \dots

Observed sequence: x

Hidden Markov model

State path:

$\pi_1 \quad \pi_2 \quad \pi_3 \quad \pi_4 \quad \pi_5 \quad \pi_6 \quad \dots$

Sequence symbols:

$x_1 \quad x_2 \quad x_3 \quad x_4 \quad x_5 \quad x_6 \quad \dots$

Transition probability:

$$a_{kl} = P(\pi_i = l \mid \pi_{i-1} = k)$$

Emission probability:

$$e_k(b) = P(x_i = b \mid \pi_i = k)$$

H: $P(\text{☀️}) = 0.7, \quad P(\text{☁️}) = 0.3$

L: $P(\text{☀️}) = 0.3, \quad P(\text{☁️}) = 0.7$

A begin state

Transition probabilities from begin state reflect prior belief:

Transition probabilities from the null state represents prior belief

Joint probability

Of the observables x and hidden states π

π_1	π_2	π_3	π_4	π_5	π_6	\cdots												
1	→	2	→	2	→	1	→	1	→	4	→	4	→	1	→	3	→	3
↓		↓		↓		↓		↓		↓		↓		↓		↓		↓
A		G		G		T		C		A		T		C		A		T
x_1		x_2		x_3		x_4		x_5		x_6		\cdots						

Joint probability of x and π :

$$P(x, \pi) = a_{0\pi_1} \prod_{i=1}^L e_{\pi_i}(x_i) a_{\pi_i \pi_{i+1}}$$

Joint probability

Of the observables x and hidden states π

$$P(x, \pi) = a_{0\pi_1} \prod_{i=1}^L e_{\pi_i}(x_i) a_{\pi_i \pi_{i+1}}$$

The probability of our sequence

Across *all* possible hidden state paths

**How likely is it that our observables are
generated by our hidden Markov model?**

The probability of our sequence

Across all possible hidden state paths

$$P(x) = \sum_{\pi} P(x, \pi)$$

$$P(x, \pi) = a_{0\pi_1} \prod_{i=1}^L e_{\pi_i}(x_i) a_{\pi_i \pi_{i+1}}$$

The probability of our sequence

Across all possible hidden state paths

$$P(x) = \sum_{\pi} P(x, \pi) \qquad P(x, \pi) = a_{0\pi_1} \prod_{i=1}^L e_{\pi_i}(x_i) a_{\pi_i \pi_{i+1}}$$

Problem: the number of paths grows exponentially with sequence length!

Luckily, we can use dynamic programming like in the Viterbi algorithm.

The probability of our sequence

Across all possible hidden state paths

$f_k(i)$ • The joint **probability** of **all state paths**
• for the first i states and i observables,
assuming that the last state is k .

The probability of our sequence

Across all possible hidden state paths

$f_k(i)$ • The joint **probability** of **all state paths**
• for the first i states and i observables,
assuming that the last state is k .

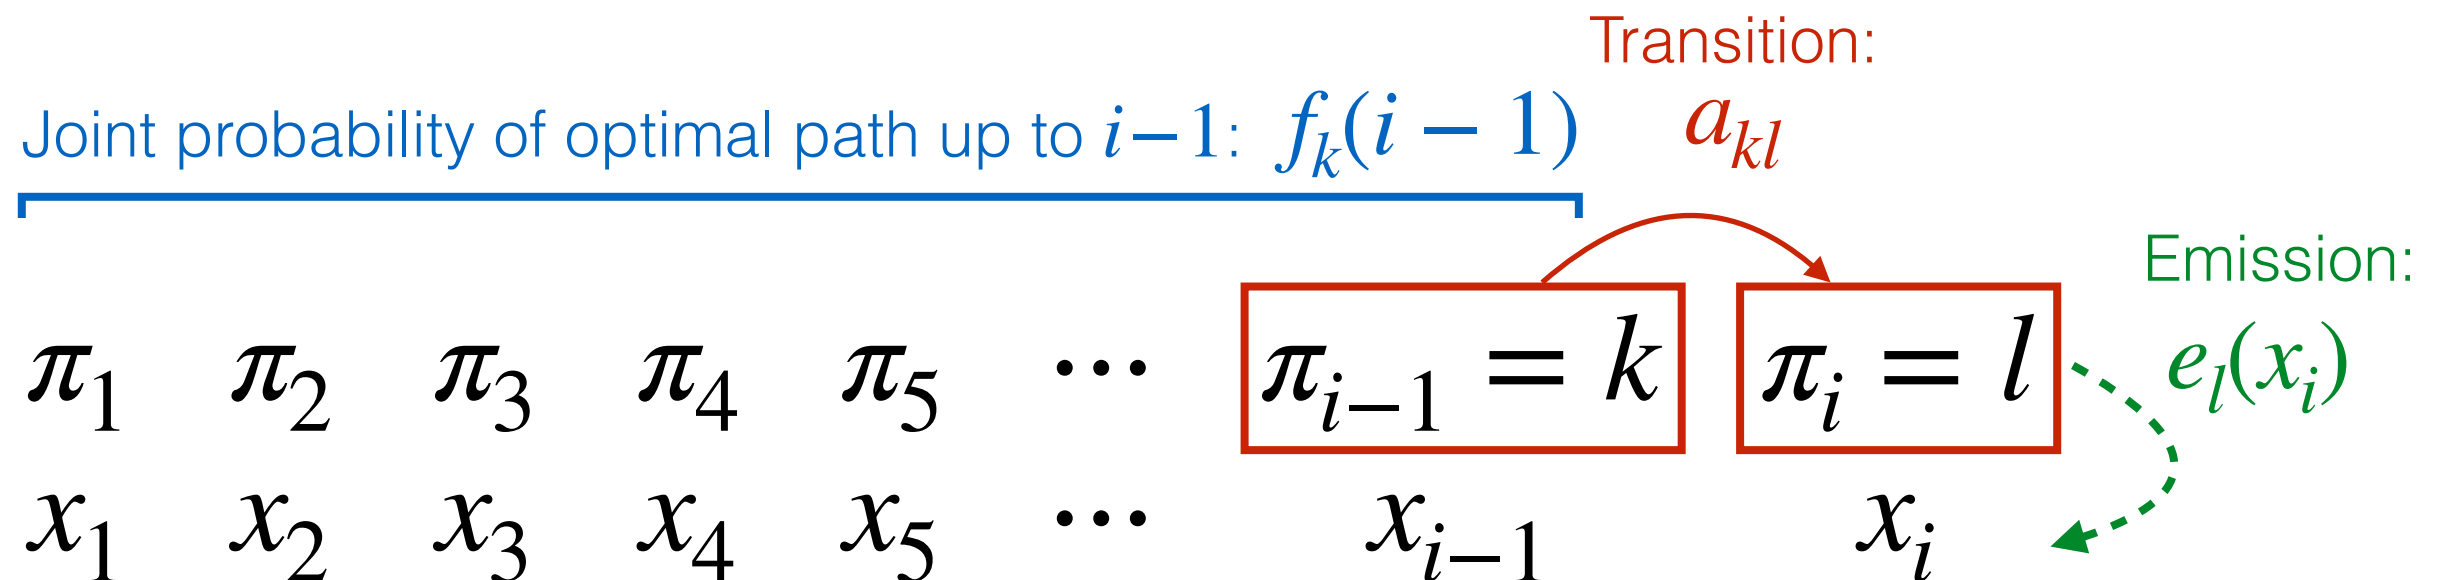

Joint probability of all paths up to i : $f_l(i)$

π_1	π_2	π_3	π_4	π_5	\cdots	$\pi_i = l$
x_1	x_2	x_3	x_4	x_5	\cdots	x_i

Most probable state path

Because of the Markov property we can compute its probability recursively:

$$f_l(i) = \sum_k f_k(i-1) a_{kl} e_l(x_i)$$

SUM
over $k \in \{1, 2, 3, 4\}$
at position $i-1$

$f_l(i)$

Recursion

Recursive case:

$$f_l(i) = e_l(x_i) \sum_k (f_k(i-1) a_{kl})$$

Base case: when no sequence is used the state is *always* the null state:

$$v_0(\mathcal{B}) = 1$$

Recursion

$$f_l(i) = \sum_k f_k(i-1) a_{kl} e_l(x_i)$$

How do we avoid computing the same probability many many times?

Remember pairwise alignment?

Dynamic programming table

for states and observables

States	\mathcal{B}	1	0	0	0	0	0	0	0	0
	1	0								
	2	0								
	3	0								
	4	0								
	Sequence	A	T	C	A	T	T	A	C	
		<i>0</i>	<i>1</i>	<i>2</i>	<i>3</i>	<i>4</i>	<i>5</i>	<i>6</i>	<i>7</i>	<i>8</i>

A red arrow originates from the sequence index 4 (under the bold 'A') and points horizontally to the state index 2 (bold '2'). The label $f_2(4)$ is placed near the arrow's midpoint.

Dynamic programming table

for states and observables

States	\mathcal{B}	1	0	0	0	0	0	0	0	0
	1	0								$f_1(8)$
	2	0								$f_2(8)$
	3	0								$f_3(8)$
	4	0								$f_4(8)$
Sequence		A	T	C	A	T	T	A	C	

Sum

Dynamic programming table

for states and observables

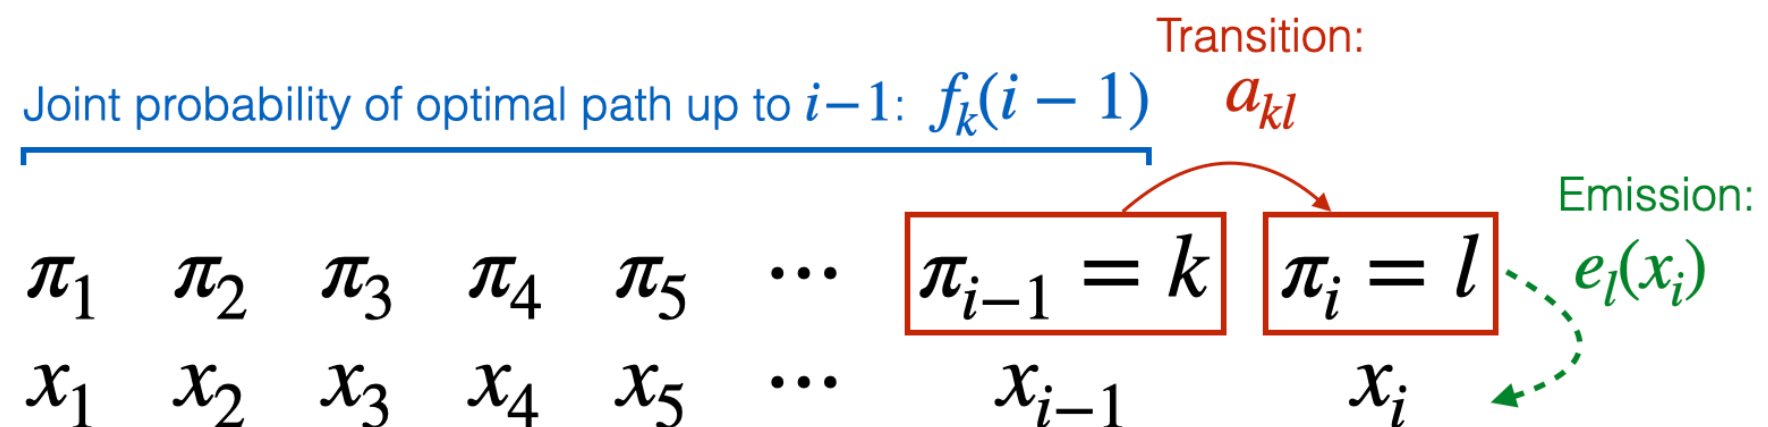

States

\mathcal{B}	1	0	0	0	0	0	0	0	0
1	0			$f_1(3)$					
2	0			$f_2(3)$	$f_2(4)$				
3	0			$f_3(3)$					
4	0			$f_4(3)$					

Sequence **A** **T** **C** **A** **T** **T** **A** **C**

Note: Red arrows point from $f_1(3)$, $f_2(3)$, and $f_4(3)$ to $f_2(4)$. A green dashed arrow points from $f_2(4)$ to the 'A' at position 5 in the sequence.

$f_2(4)$ is the sum of joint probabilities for all hidden state paths ending at state **2** at position 3.

Dynamic programming table

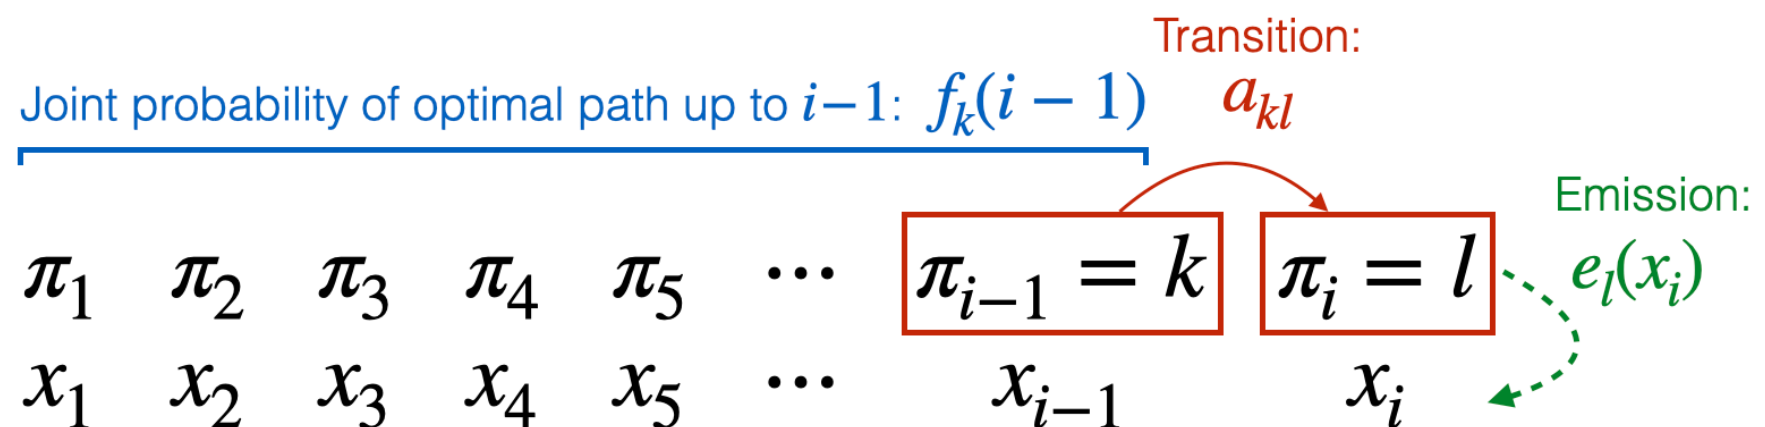

for states and observables

States

\mathcal{B}	1	0	0	$f_{\mathcal{B}}(3)$	0	0	0	0	...
1	0			$f_1(3)$					
2	0			$f_2(3)$	$v_2(4)$				
3	0			$f_3(3)$					
4	0			$f_4(3)$					

Sequence **A** **T** **C** **A** **T** **T** **A** **C**

Formally, we sum over all k including \mathcal{B} , but since $f_{\mathcal{B}}(i) = 0$ for $i > 0$, we can safely ignore it.

Dynamic programming table

for states and observables

States	\mathcal{B}	1	0	0	0	0	0	0	0	0
	1	0								$f_1(8)$
	2	0								$f_2(8)$
	3	0								$f_3(8)$
	4	0								$f_4(8)$
Sequence		A	T	C	A	T	T	A	C	

Fill the table column by column, from left to right

Sum

Backward algorithm

$$b_l(i) = \sum_k a_{kl} e_l(x_{i+1}) b_k(i+1)$$

Posterior probability

- of a state at a position in the sequence

The proportion of the total probability contributed by paths with state k at position i :

$$P(\pi_i = k | x) = \frac{P(\pi_i = k)}{P(x)} = \frac{f_k(i) b_k(i)}{P(x)}$$

Posterior decoding

Hidden states with max posterior probability

Posterior probability that the state at position i is k :

$$P(\pi_i = k \mid x) = \frac{f_k(i) b_k(i)}{P(x)}$$

Important: Contributions from many different paths. So the sequence of states with the highest posterior probability will not correspond to a valid path through the state model.

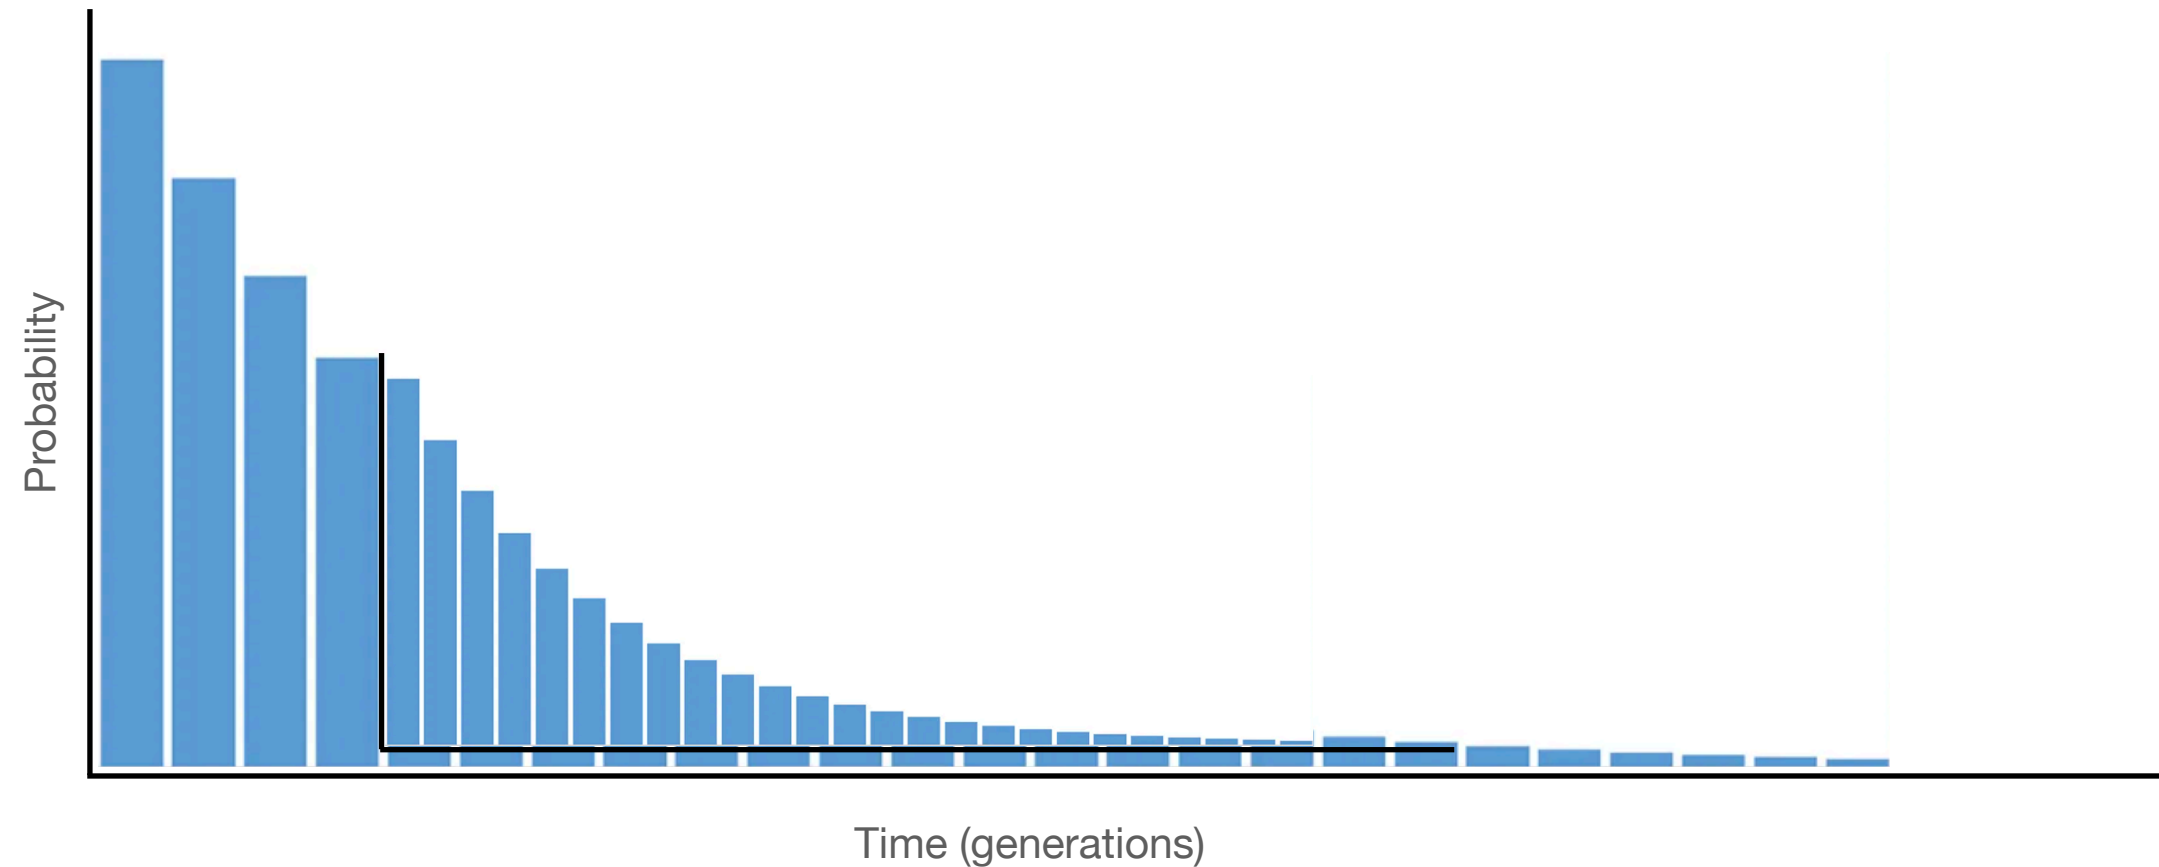

Demography with PSMC

Suppose we knew the TMRCA of each sequence segment

Thought experiment

Suppose we knew the TMRCA of each sequence segment

Thought experiment

Suppose we knew the TMRCA of each sequence segment

Back to reality

- But don't despair

- We **do not** have:
 - The segments between recombination events.
 - The TMRCA of each segment.
- We **do** have:
 - The sequence differences.
 - A model (the ARG) that relate sequence differences to segment length and TMRCA.

Mutations and TMRCA

Which segment has the longest TMRCA?

- Why?

Mutations and TMRCA
